TITLE: Luminescence kinetics of divalent samarium in single crystals of strontium and barium fluorides

PERIODICAL: Optika i spektroskopiya, v.13, no.2, 1962, 294-296

TEXT: The object of this work was to confirm the results of earlier work (Opt. i spektroskopiya, v.12, 1962, 493) and in particular to give detailed quantitative data on the luminescence kinetics of the  $\text{Sm}^{2+}$  ions in the single crystals of  $\text{SrF}_2$  and  $\text{BaF}_2$  and the explanation of the interaction of 5d and 4f configurations. An impulse taumeter designed by Tolstoy was used to find the relations between the duration of luminescence and the radiated wavelength. Luminescence was excited with the help of an impulse light modulator giving 10 impulses per sec. It was found that the thermal equilibrium between the states of the 4f<sup>5</sup> 5d configuration and the  $^5\text{D}_0$  level of the 4f<sup>6</sup> configuration was established within a time considerably shorter than the average duration of the excited state and hence the aggregate of the excited levels could be considered as a single system. From

Card 1/2

Luminescence kinetics ...

their premises the authors developed an approximate equation describing the kinetics of the deactivation of the excited state the solution of which gave the exponential kinetic of luminescence. It was concluded that the above type of luminescence occurs during the transitions from two excited energy systems which are in mutual thermal equilibrium. Irrespective of the existing differences in the population of these systems, the intensities of their radiation within the determined temperature interval were comparable as a result of sharp differences in the probabilities of the radiative transitions. The sharp fall in the intensity of luminescence from the  $5D_0$  levels with temperature was explained by the shift of the electrons from the  $5D_0$  levels to the levels of the  $4f^5 5d$  configuration.

LUMINESCENCE AND STIMULATED EMISSION OF NEODYMIUM-  
ACTIVATED GLASS (USSR)

Feofilov, P. P., A. M. Bonch-Bruyevich, V. V. Vavilov, Ye. A. Imas, G. O. Karapetyan, Ye. V. Nekrasov, and M. N. Tolstoy, IN: Akademiya nauk SSSR, Izvestiya, Seriya fizicheskaya, v. 27, no. 4, Apr 1963, 466-472.

S/048/63/027/004/002/026

Studies of luminescence and induced emission of neodymium-doped glass have been carried out, and optimum glass composition was determined. Glasses were developed which are superior to those used by B. Salin. Absorption and luminescence spectra were obtained, and the dependence of the duration of luminescence on concentration was determined. Induced emission was observed both in glass fibers encased in glass and in small homogeneous glass cylinders. The dependence of time characteristics of the spectral composition of induced emission on pumping energy was determined. The prospects of application of the material to practical lasers are discussed. The prospects of induced emission phenomena are discussed.

TITLE: Removal of the degeneration of energy levels of cubic activation centers in mixed crystals of the fluorite type

SOURCE: Optika i spektroskopiya, v. 19, no. 5, 1965, 812-814

TOPIC TAGS: mixed crystals, fluorite, IR spectrum, luminescence spectrum, rare earth metal, single crystal, spectral line, line width, line splitting

ABSTRACT: According to the literature (D. S. McClure, Z. Kiss, J. Chem. Phys., 39, 3251, 1963; P. P. Feofilov, Electron. Quant., C. R. 3<sup>e</sup> Conf. internat., Paris. - N. I. 1964, p. 1079; Acta phys. polon., 26, 331 1964), the degeneration of the energy level, which usually decreases in the fields of a lower symmetry, is partially retained in crystals of the fluorite type because of a high symmetry of the intercrystalline field ( $Q_1$ ) surrounding the bivalent ions of an activator (rare earth elements) isomorphically intruding into the fluoride-type crystals.

A study was made of the infrared luminescence spectra of single crystals in the system  $\text{Ca}_x \text{Sr}_{1-x} \text{F}_2$  ( $x=0, 0.1, 0.25, 0.5, 0.75, 0.9$ , and  $1.0$ ) activated by 0.1 mole%  $\text{Dy}^{++}$ ,  $\text{Tu}^{++}$ , and  $\text{Ho}^{++}$ . Measurements were made at 77K. The simplest changes of the spectrum (with changed composition) were observed in crystals activated by  $\text{Dy}^{++}$ , where the widened lines were monotonically displaced from one extreme position to another. At  $x=0.5$  the lines widened to a degree that the adjacent lines could not be resolved. The absence of sharp changes was attributed to the absence of degeneration related to the presence of an inversion center. The spectra of the crystals activated by  $\text{Tu}^{++}$  and  $\text{Ho}^{++}$  were more complex. Two intensive lines, having  $\lambda=1.116$  and  $1.189 \mu$  ( $\text{CaF}_2$ ) which corresponded to the Stark components of the terms  $^2\text{F}_{5/2}$  were observed in single-component crystals activated by  $\text{Tu}^{++}$ . In mixed crystals the first line monotonically displaced (with changes in  $x$ ), whereas the second line was split in two with the maximum degree of splitting ( $\sim 50 \text{cm}^{-1}$ ) at  $x=0.5$ . The splitting of lines reflected the twofold degeneration of the energy level which can be removed at the expense of a relatively small distortion of symmetry caused by replacements in the cation coordination sphere. The duration of the luminescence of  $\text{Tu}^{++}$  was the same ( $\sim 7 \text{ m sec}$ ) in the single and mixed crystals. This indicated the magnetic-dipole character of the luminescence of  $\text{Tu}^{++}$ . The emission spectrum of  $\text{Ho}^{++}$  in single

Card 2/3

L 17879-66

ACC NR: AP5027676

$\text{MeF}_2$  crystals consisted mainly of the two intense lines in the region  $1.82-1.83 \mu$ . In mixed crystals both lines were split by  $\sim 12 \text{cm}^{-1}$ . The short-wave components of splitting disappeared at the He temperatures. This suggested that the emitting level in the  $\text{MeF}_2\text{-H}^{+}$  was the same component of the therm  $^4\text{I}_{13/2}$  subjected to fourfold degeneration (G). The components of the main therm  $^4\text{I}_{15/2}$  were twofold degenerated ( $\text{E}_{1/2}$  and  $\text{E}_{3/2}$ ). The authors thank A. N. Terenina for her interest in the work. TITLE: Luminescence of neodymium and chromium in an yttrium-aluminum garnet

SOURCE: Optika i spektroskopiya, v. 19, no. 5, 1965, 817-819

TOPIC TAGS: spectroscopy, crystal lattice structure, luminescence, neodymium, chromium, yttrium, crystal growing, single crystal

ABSTRACT: Crystals of Y-Al garnet (YAG) were grown in a fluoride and lead oxide melt. Neodymium and chromium were added to the melt in the form of oxides to activate the crystals, and the infrared luminescence spectra of the YAG-Nd single crystals were determined in the regions of all four groups of radiations, situated near 0.9, 1.1, 1.4, and 1.8  $\mu$  and corresponding to the transition from the excited  $^4F_{3/2}$  term to the terms  $^4I_{9/2-15/2}$ . The spectra were taken at 77K by the diffraction spectrometer with receiver from PCS and the radiations of the first group were, in addition, photographed on I-920 film in a spectrograph with a

1/2

UDC: 535.37 : 548.0

L 15764-66  
ACC NR: AP5027677

dispersion of  $\sim 13$   $\text{Å/mm}$ . The value of splitting of the  $^{4}\text{F}_{3/2}$  ( $\Delta E=84\text{cm}^{-1}$ ) was much larger than that of the lanthanum halides and scheelite crystals. This indicated the larger force of the intercrystalline field, which was substantiated by the splitting values of the  $^{4}\text{I}$  terms. But the relative splitting of individual  $^{4}\text{I}$  terms was the same as in the scheelite and other bases: the largest splitting was observed in the  $^{4}\text{I}_{15/2}$  and  $^{4}\text{I}_{9/2}$  terms ( $976$  and  $857\text{ cm}^{-1}$ ). It was noticeably smaller in the  $^{4}\text{I}_{13/2}$  and  $^{4}\text{I}_{11/2}$  terms ( $574$  and  $518\text{ cm}^{-1}$ ). The study of Nd luminescence was facilitated by the presence of  $\text{Cr}^{3+}$  in the crystals, which sensitized the luminescence of  $\text{Nd}^{3+}$ . The absorption spectrums of  $\text{Cr}^{3+}$  in YAG were described by D. J. Wood et al. (J. Chem. Phys., 39, 890, 1963). The effect of the sensitization of Nd luminescence by  $\text{Cr}^{3+}$  was proven both by spectral and by kinetic studies. The results agreed entirely with those of Z. J. Kiss and R. C. Dunkan (Appl. Phys. Lett., 5, 200, 1964) on the nonradiative resonance transfer of YAG of excitation energy from chromium to neodymium ions. Orig. art. has: 2 figures.

TITLE: Luminescence and stimulated emission of neodymium in fluoberyllate glasses

SOURCE: Optika i spektroskopiya, v. 21, no. 1, 1966, 126-128

TOPIC TAGS: stimulated emission, luminescence spectrum, neodymium, fluoberyllate glass, *BERYLLOUM COMPOUND, GLASS*ABSTRACT: The luminescence and stimulated emission of the  $Na^{3+}$  ion were studied in fluoberyllate glasses of the following compositions:

- 1)  $BeF_2$ —60;  $AlF_3$ —10;  $CaF_2$ —10;  $KF$ —15;  $MF$ —5% (M = Li, Na, K, Rb, Cs, Ti).
- 2)  $BeF_2$ —70;  $AlF_3$ —10;  $MF$ —2% (M = Li, Na, K, Rb, Cs).
- 3)  $BeF_2$ —60;  $AlF_3$ —10;  $KF$ —20;  $CaF_2$ —5;  $MF_2$ —5% (M = Mg, Ca, Sr, Ba, Zn, Cd, Pb).

Since the absorption and luminescence characteristics of all the glasses were found to be very similar (only glasses containing Li had substantially wider emission bands), the data obtained in the study are considered typical for fluoberyllate glasses of the most diverse compositions. The luminescence spectrum of  $Na^{3+}$  is shown in Fig. 1. Its

Card 1/3

UDC: 535.37:546.657:666.1/2

L 41100-66  
ACC NR: AP6025970

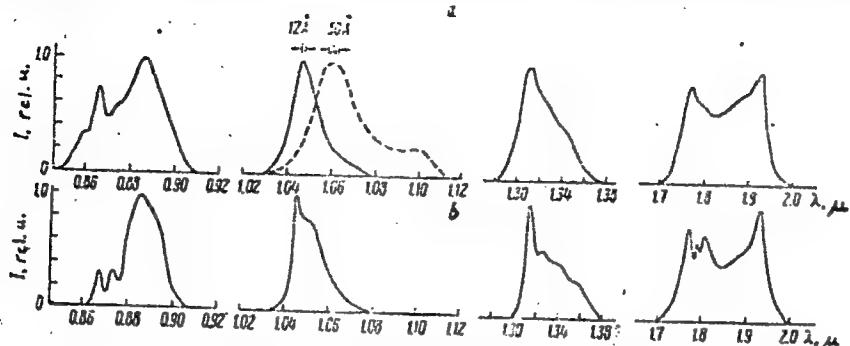

Fig. 1. Luminescence spectra of  $\text{Nd}^{3+}$  in fluoberyllate glasses at 300 (a) and 77°K (b). Intensity maxima in the various groups are normalized to unity. Broken line indicates the luminescence spectrum of Nd in silicate glass. The regions of generation of stimulated emission are marked.

comparison with spectra of  $\text{Nd}^{3+}$  in other matrices shows that although in fluoberyllate glasses the half-width of bands corresponding to transitions between the individual splitting components of the terms substantially exceeds that observed in crystals, the bands in these glasses are nevertheless much narrower than in oxygen-containing (for example, silicate) glasses. A second characteristic feature of Nd spectra (and other

Card 2/3

1. 41100-66  
ACC NR: AP6025970

rare earth ions) in fluoberyllate glasses is the relatively small "crystalline" splitting of terms, as a result of which the groups of luminescence bands are more compact. The force of the field acting on  $Nd^{3+}$  ion in fluoberyllate glasses was found to be small. Generation of stimulated emission was observed at room temperature in cylindrical specimens 40 mm long and 3.5-5.0 mm in diameter, prepared from glass containing 2 mole %  $NdF_3$ . The spectrum of this emission consists of a large number of close narrow lines. The center of the region of generation corresponds to 10,473 Å, i. e., it is located near the maximum of the luminescence band. Thus, the region of generation in fluoberyllate glasses is shifted by more than 100 Å toward the shortwave side as compared to silicate glasses. Orig. art. has: 2 figures. [27]

ABSTRACT: The department of geology and mineralogy at the Timiryazev Agricultural Academy was organized in 1865. Its history is associated with the names of such scientists as I. B. Auerbach -- the first professor of the department; G. A. Trautschold -- chairman of the department for 22 years; A. P. Pavlov -- docent, and later a professor of the department from 1889 to 1892; Ye. S. Fedorov; Ya. V. Samoylov; M. I. Kantor, and others. The first three men are associated with a thorough study of the geological structure of the Moscow region. A. P. Pavlov worked on the basic problems of

Ninetieth Anniversary of the Department of (Cont.)

contemporary biostratigraphy, on depicting the geological structure of the Russian Plain, on the subject of the Quaternary system, and the processes leading to the formation of continental strata. Many of the classic works on crystallography were completed in the Timiryazevskaya Academy by Ye. S. Fedorov. Ya. V. Samoylov contributed much to the study and locating of mineral concentrations, particularly of phosphorites. He created a new scientific discipline--mineral fertilizers--the connecting link between geology and agriculture. M. I. Kantor dedicated much knowledge and energy to the study of the Kerchenskiye phosphoric iron ores. After his death (1946), the department was headed by A. A. Dubyanskiy, A. I. Kravtsov, and N. N. Lushchikhin.

TITLE: Report on the Scientists Who Have Held the Chair of  
Geology and Mineralogy at the Timiryazevskaya Academy  
(Vklad v nauku uchenykh kaferdy geologii i mineralogii  
Timiryazevskoy akademii)

PERIODICAL: Dokl. Mosk. s.-kh. akad. im. K. A. Timiryazeva, 1956,  
Nr 25. pp 40-45.

ABSTRACT: The Timiryazevskaya Agricultural Academy used to be  
called the Petrov Farm and Forest Academy; its chair  
of Geology and Mineralogy was created in 1865. The  
first professor to hold this chair was I. B. Auerbach  
(1815-1867), who studied the Cretaceous deposits of the  
Moscow region. His successor was G. A. Trautshold (1817-  
1902), whose specialty was the basic flora and fauna of  
the Carboniferous, Jurassic, Cretaceous, and Quaternary

Card 1/2

deposits. He demonstrated the importance of loams and alluvial soils for agriculture, and called for the utilization of mineral fertilizers. Ye. S. Fedorov held the post from 1895 to 1905. During these years he worked out the theodolitic method for use in crystallography and devised a crystallochemical analysis employing this method. Professor of the Academy, S. G. Voyslov (1850-1904), did much for the popularization of geological knowledge and for the development of oil drilling in Russia. From 1906 to 1925 the chair was occupied by Professor Ya. V. Samoylov, who was famous before the Revolution for his investigations of phosphorite deposits and who organized the Scientific Institute of Fertilizers. He was an expert on mineral fertilizers and bioliths and he opened up new fields in geology--biogeochemistry and contemporary marine geology. Samoylov's successors in this post were M. I. Kantor, Professor A. I. Kravtsov, and Docent N. N. Lushchikhin, who continued Samoylov's work on mineral fertilizers.

Birefringence in the flow of isotropic liquid *p*-azoxyanisole. N. Tolstoi (Compt. rend. Acad. Sci. U.R.S.S., 1944, 63, 107-111).— Birefringence ( $\alpha$ ) and extinction angle ( $\beta$ ) for *p*-azoxyanisole (I) have been measured from 133° (the transition temp.) to 157°.  $\alpha$  and Maxwell's const. increase with temp.  $\beta$  is 48° and is independent of the temp. and manner of flow. The sign of  $\alpha$  is positive in the Maxwell and Cotton-Mouton effects. Application of the Stuart-Peterlin theory (A., 1939, I, 318) shows the group uniting the (I) mols. to be stretched 1-3 times in the axial direction of the mols. packed parallel into the group. The group contains a few hundred mols.; its size is  $10^4$ - $10^5$  times  $<$  that usual for groups in anisotropic phases. J. O'M.B.

ASA-1A METALLURGICAL LITERATURE CLASSIFICATION

sal. N. A. Tolstoy and L. N. Fedotov (Milit. Aviation Eng. Acad., Leningrad). *J. Russ. Theoret. Phys.* (U.S.R.), 17, 604-70 (1947) (in Russian).—Measurements of the angle of extinction  $\chi$  (angle between the axis of the flow birefringence and the direction of the flow) in a rotating Couette-type app., confirmed the perfect constancy (within  $1/10$ ) of  $\chi = 45^\circ$  at all rates of shear  $g$  up to  $11,000 \text{ sec.}^{-1}$ , throughout the whole accessible range (a level above  $32^\circ$  (the transition point of  $\alpha$ -xanthydrol); consequently, in this respect, the crystal liquid in the isotropic state behaves like a normal mol. liquid. This was confirmed in both the region of laminar flow ( $g$  up to  $1380 \text{ sec.}^{-1}$  at a clearance between the rotor and the outer cylinder of  $0.03 \text{ mm.}$ ) and in turbulent flow ( $g = 1800-11,000 \text{ sec.}^{-1}$ ), also with a clearance of  $1.3 \text{ mm.}$  for both types of flow. In contrast thereto, the magnitude of the flow birefringence  $\Delta n$  is of a much higher order than with the normal liquids. At each const. temp., it rises linearly with  $g$ , the less steeply the higher the temp., between  $133^\circ$  and  $187^\circ$ ; the variation is the faster the closer the temp. to the point of transition into the anisotropic state. It also indicates absence of satn. As a function of temp., close to the transition point. The Maxwell const.  $M = \Delta n/\Delta \eta$  (with  $\eta = 1.04$ ), plotted against the temp. between  $133^\circ$  and  $187^\circ$ , almost coincides with the curve of the Colton-Mouton const.  $C = \Delta n/\eta^{1/2}$  for magnetic birefrin-

fective  $\lambda_1$ ,  $\lambda_2$ , the two curves are made to coincide at  $\lambda = 137^\circ$ , the  $C$  curve, plotted with the data of Zastoc-Kahn (C.A. 15, 553), is somewhat above the  $\lambda$  curve below that temp., and somewhat below  $M$  above  $137^\circ$ . Thus, despite the normality of  $x$ , isotropic  $\beta$ -asoyanamide exhibits  $M$  values of the order of  $10^{-3}$  at even as high as  $160^\circ$ , as against  $M = 4.8 \times 10^{-11}$  for  $\text{C}_6\text{H}_5\text{CO}_2$ ; consequently, in this respect,  $\beta$ -asoyanamide behaves as a colloidal soln. This behavior can be described in terms of the theory of Peterlin noninteracting clusters, colloidal particles, or polymerized mols. large enough to be unaffected by thermal agitation and of normal monomeric mols. subject to forces of interaction and to Brownian motion; on this assumption, the Maxwell effect of the mol. of the 2nd kind can be disregarded and be called, for those of the 1st kind. Use revolution-ellipsoidal particles, the elongation  $\beta = a/b$  is found from the combined formulas for  $M$  and  $C$ ; with the experimentally ded. values of  $M$  and  $C$ ,  $\beta = 1.25$  and  $1.47$  at  $134^\circ$  and  $160^\circ$ , resp., i.e., the clusters are much less elongated than the single mol. ( $\beta \approx 5$ ). The theory further supplies the upper limit for the av. vol. of a cluster,  $v_{max} = 2.5 \times 10^{-10}$  cc. at  $134^\circ$ ; the vol. of 1 mol. at temp. is at most  $= 7000$ . To this max. size of a cluster corresponds a min. concn.  $c_{min} > 0.8\%$  and  $> 0.72\%$  at  $134^\circ$  and  $160^\circ$ , resp. On the other hand, the same birefringence effects can be due to clusters of smaller size present at a higher concn.; the uppermost conceivable limit of the latter being  $c_{max} = 100\%$ , the corresponding smallest vol.  $v_{min} > 2.1 \times 10^{-10}$  and  $> 1.8 \times 10^{-10}$  at  $134^\circ$  and  $160^\circ$ , resp., corresponding to  $> 435$  and  $> 48$  mols., resp., per cluster. Thus, the clusters in the isotropic phase are at any rate substantially smaller than the swarms present in the anisotropic state ( $\sim 10^{-11}$  cc.) which are also more elongated ( $\beta = 2$ ). N. Thos.

CIA-RDP86-00513R001756120016-2"

Long-range fluctuations in the isotropic phase of para-  
polymer. N. A. Tolok (State Optical Inst., Leningrad). *J. Exptl. Theor. Phys. (U.S.S.R.)* 17, 724-8 (1947) (in Russian); cf. *C.A.* 42, 1090e.—The abnormally steep rise of flow and magnetic birefringence on approaching the isotropic-anisotropic transition temp. is interpreted on the basis of Preukel's (ibid. 9, 933 (1939)) theory of heterophase fluctuations. It is assumed that "long-range groups," or germs of the long-range order characteristic of the anisotropic phase, are formed to some extent in the isotropic phase, and that at high temps. the latter consists of a single sort of smaller "near-range groups" the aggregation of which, at lower temps., produces the larger long-range groups; these, in contrast to the near-range groups, vary in size by multiples of  $g_0$ , the no. of mols. in a near-range group. The no. of groups of  $g$  mols. each, at the temp.  $T$ , is given by the distribution function  $f = f_0 e^{-\lambda(T - T_0)/2T}$  where  $T_0$  = transition temp.  $\lambda$  = heat of transition, and the mean size of a long-range group is given by  $\bar{g} = \sum g f / \sum f$ , the summations to be extended from  $g = g_0$  to  $g = \infty$ . The correct value of  $g_0$  is deduced from the exptl. data, by plotting the calcd.  $\bar{g}$  against the temp. on the assumption of various  $g_0$  and comparing with the exptl. curve  $\bar{g} = C \times 10^{14} (T/T_0)^{2/3} (g_0 - g_0)(x_1 - x_0)$ , where  $C$  = Cotton-Mouton const.,  $x$  =

refractive index,  $v_0$  = vol. of a mol.,  $g_1 - g_0$  = optical anisotropy factor,  $x_1 - x_0$  = difference of magnetic susceptibilities. At lower temps., up to about  $T - T_0 = 6^\circ$ , all calcd.  $\bar{g}$  curves are merged into one, irrespective of the  $g_0$  assumed, but they diverge with increasing  $T - T_0$ ; the calcd. curve coincides with the exptl. for  $g_0 \approx 25$ . This is the approx. no. of mols. that can possibly constitute a "long-range group"; it can be conceived as a single layer of  $5 \times 5$  mols. and, on the other hand, corresponds to the least no. of mols. necessary to form an approx. spherical package. N. Thon

Kerr effect in *cis*-sorbons of *p*-azoxyanisole and *p*-azoxymethane. N. A. Tolstol. *Zhur. Ekspd. Tverst. Fiz.* 19, 319-37 (1949). The available body of facts relative to the anisotropy of the dielec. const. in liquid crystals, in particular the results of Kast (C.A. 22, 912; 25, 5807), W. Mayer (*Ann. Physik* 33, 210 (1928)), Marinakis and Tsvetkov (C.A. 34, 46254), etc., leaves no doubt about their greater polarizability perpendicularly to the axis, but the question of the position of the permanent dipole moment relative to the mol. remains open. An answer was provided by measurements of the Kerr const.  $K = (n_s - n_i)/nE^2$ , where  $n_s$ ,  $n_i$ ,  $n$ , are, resp., the mean, longitudinal, and transverse  $n$ , and  $E$  = elec. field strength. From the Langevin-Iorn theory of the Kerr effect, it follows that, with  $K^{\text{par}}$  and  $K^{\text{per}}$  denoting, resp., the Kerr const. corresponding to the dipole moment oriented parallel and perpendicular to the axis of the mol., the angle  $\alpha$  between the dipole moment and the axis is given by  $\alpha = \text{arc cot } \sqrt{(K - K^{\text{per}})/(K^{\text{par}} - K)}$ . In soln., the Kerr const.  $K^{\text{p}}$  per 1 mol. is related to the Kerr const.  $K$  of the soln., of the solvent ( $K_1$ ), and the Kerr const.  $K^{\text{p}}$  per 1 mol. of the solvent, by  $K^{\text{p}} = (1/\epsilon N)(K - K_1)M_1/\rho_1 + K_1M_1/\rho_1$ , where  $\epsilon$  = viscosity of the soln.,  $\rho$  = d.,  $M$  = mol. wt., and  $N$  = Avogadro's no. Measurements on *p*-azoxymethane (I) in soln. in  $\text{C}_6\text{H}_6$  confirmed the linearity between  $K$  and  $K^{\text{p}}$ , and the pos. sign of  $K$  for I, the Kerr effect of the soln. being 18% greater than of the pure solvent. In solns. in  $\text{C}_6\text{H}_6$ , with  $\epsilon$  varying from 0.0071 to 0.0187, the value for I is, independently of the concen.,  $K^{\text{p}} = (3.7 \pm 0.2) \times 10^{-11}$ ,

and in soln. in  $\text{CCl}_4$  ( $\epsilon$  varying from 0.0044 to 0.0109)  $K^{\text{p}} = (4.5 \pm 0.9) \times 10^{-11}$ ; for *p*-azoxymethane in  $\text{C}_6\text{H}_6$ ,  $K^{\text{p}} = (1 \pm 0.2) \times 10^{-11}$ . With the known values of the sp. refractions and polarizabilities, one finds, by the Langevin-Born formulas, for I,  $K^{\text{per}} = 23.3 \times 10^{-11}$ ,  $K^{\text{par}} = -7.12 \times 10^{-11}$ , and, consequently,  $\alpha = 56^\circ$  (in  $\text{C}_6\text{H}_6$ ) and  $\alpha = 57.3^\circ$  (in  $\text{CCl}_4$ ); for II, in  $\text{C}_6\text{H}_6$  soln.,  $\alpha = 60.5^\circ$ . In this range,  $\alpha$  is relatively little sensitive to the value of  $K^{\text{p}}$ , and an error in the latter has consequently little effect on  $\alpha$ . The result means that the dipole moment is neither parallel nor perpendicular to the axis of the mol., but forms an angle of the order of  $45^\circ$  with the azoxy group. Consequently, the dipole moment has a substantial component in the direction perpendicular to the axis. This bears out Tsvetkov's (*Acta Physicochim. U.R.S.S.* 3, 866, 870 (1935); *Izv. Akad. Nauk S.S.R., Ser. fiz.* 5, 57 (1941)) interpretation of the large elec. polarizability of anisotropic-liquid I in a swarm, which merely calls for the existence of a perpendicular component, but is not inconsistent with a parallel component of the dipole moment. Inasmuch as a swarm as a whole has no dipole moment, the mols. in it are disposed as frequently with the longitudinal component in one as in the opposite direction. An elec. field perpendicular to the axes of the mols. will tend to split the swarm at points where neighboring mols. have antiparallel longitudinal components, and this effect will be particularly strong between 2 groups of mols. parallel within each group but antiparallel from one group to another. Consequently, application of an elec. field may result in a shake-up of the existing swarm pattern into a new swarm array. N. T.

"New Method of Studying Relaxation Processes," N. A. Tolstoy, P. P. Feofilov, State Optical Inst., 10 pp.

"Zhur. Eksp. i Teoret. Fiz." Vol XIX, No 5

PA 46/49199  
Describes new oscillographic method of studying relaxation of physical processes, based on the use of nonlinear graphing. Method is applicable to processes occurring in the time interval  $10^{-6}$ - $10^{-1}$  sec. In the case of relaxation taking place according to the exponential law ( $\exp -t/\tau$ ), value of  $\tau$  may be determined after several seconds. Generalization of method, called "the method of partial time," is applicable to processes in which relaxation occurs according to any law. Submitted 6 Nov 48.

"Application of the New Method for Studying Relaxation Processes to a Study of Relaxation Polarization in Dielectrics," G. I. Skanavi, N. A. Tolstoy, P. P. Feofilov, K. I. Lebedev, Phys Inst imeni Lebedev, Acad Sci USSR, 9 pp

"Zhur Eksper i Teoret Fiz" Vol XIX, No 12 p. 1121-9

To study relaxation polarization in dielectrics of titanium dioxide with small additions of oxides of metals belonging to the second group of the periodic table (this group gives very high values of  $\epsilon$  in the region of low frequencies), one employs the oscillographic method of studying, by electrical square-wave impulses through ohmic resistances, the charge and discharge of the condensers containing the dielectric under study. Here a simple exponential development of the process in time is employed, as well as more complicated ones. Shows charge and discharge processes of the condenser with the dielectric under study have a complex character differing from the exponential. Equivalent circuit schemes are found for the dielectrics under study. Parameters of these schemes are determined experimentally. Calculation of these equivalent schemes permits one to obtain the function of current drop with time in each studied dielectric with calculated constants and thus to evaluate values of initial currents. 1304. Discontinuities in the conductivity of  $\text{BaTiO}_3$ ,  
N. A. Tolstoy. *J. Tech. Phys., USSR*, 20, 970-4  
(Aug., 1950) *In Russian.*

Characteristic discontinuities are of two types, i.e., one connected with surface phenomena (rapid leaps), the other with volume phenomena (*x*-type leaps). The high permittivity of  $\text{BaTiO}_3$  (1 600-2 000) raised doubt whether or not it constituted a ferroelectric at all. A smoothly increasing field applied to an artificial single-crystal produces a discontinuous polarization. The macroscopic domains of the crystal charge orientation at certain field values corresponding to certain energy barriers to be overcome. At temperatures above the Curie point these phenomena disappear. The analogy with the discontinuities of the magnetic polarization in ferromagnetics caused these phenomena to be called "electric Barkhausen discontinuities." A point of particular interest is that  $\text{BaTiO}_3$  is a polycrystalline substance.

*The relaxation time for the luminescence of copper oxide and its temperature dependence. N. A. Tolstof and N. N. Tkachuk. Doklady Akad. Nauk S.S.R. 95, 65-8 (1954)*

The relaxation time of  $\text{Cu}_2\text{O}$  was measured by means of an ultrataurometer which is described in detail and which registers inertia of the order of  $1 \times 10^{-4}$  sec. The measurements were made over temp. range  $-183-20^\circ$ . The relaxation time  $\tau$  was found to increase with increasing temp. by a factor of 20-40 in the given range. This anomalous temp. dependence excludes the possibility of a monomol. mechanism for the luminescence of  $\text{Cu}_2\text{O}$ . The following conclusions are drawn:  $\text{Cu}_2\text{O}$  luminescence is due to a recombination mechanism with a large difference in the no. of recombining partners (free electrons are fewer than luminescence centers); the lifetime of a center is  $3-4 \times 10^{-6}$  sec.; the lifetime of an electron in the band of cond.  $< 3 \times 10^{-4}$  sec. at  $-183^\circ$  and increases to  $\approx 10^{-3}$  sec. at room temp.

Some details of the luminescence kinetics of the ZnS-Cu phosphors. N. A. Tolstoy. *Doklady Akad. Nauk S.S.R.* 62, 95, 240-52 (1954).—The phosphorescence of the ZnS-Cu phosphor cannot, apparently, be explained by the simple bimol. or the simple unimol. theories, and in order to simplify the studies was investigated experimentally (1) under conditions of rapid extinction at high temp., and (2) under the initial relaxation conditions. The present report covers only the 1st part of the investigation. An investigation of the extinction leads to the conclusion that the mechanism of the phosphorescence phenomenon of ZnS phosphor is bimol. at a high temp., and that the exciting light has also an extinguishing effect. Title : Instrument for Measurement of Relative Pulsations of Light Fluxes.

Orig Pub: Svetotekhnika, 1955, No 2, 27-29

Abstract: Description of a method and of an instrument for rapid objective measurement of the relative pulsations of light flux. The direct purpose of the instrument is the measurement of the stroboscopic effect of fluorescent lamps. The studied light flux is received by an antimonycesium photocell (equipped with light filters, including a light filter that "equates" the photocell to the eye). The signals from the photocells are received by a dc amplifier, fed from the power line. A dividing network on the output of the amplifier separates the purely alternating portion of the signal

and its dc component, and these are applied respectively to two pointer meters. Normalizing the coefficient of amplification of the dc components to unity (setting the pointer of the second instrument at the "red marker"), one obtains the value of the relative pulsations of the light flux by directly reading the first pointer instrument. The accuracy of the "strobometer" is better than 1%.

Title : Rigid dipole moment of aerosol particles

Periodical : Zhur. eksp. i teor. fiz., 29, September 1955, 385

Abstract : New methods of investigating electro-optical phenomena in hydrophobe colloids (N. A. Tolstoy, P. P. Feofilov, DAN SSSR, 66, 617, 1949; N. A. Tolstoy, DAN SSSR, 100, 893, 1955) which are based on the study of the modulation of light passing perpendicularly to the lines of an electric field through a planar condenser fed by rectangular voltage impulses show that colloidal particles in aqueous media possess rigid dipole moments of quite considerable magnitude. It is assumed that this rigid dipole moment is caused by spontaneous orientation of water molecules adsorbed on the surface of the particle, which have a rigid dipole. The unipolarity (in the mean) of this orientation permits one to liken the water film adsorbed on the particle to a surface piezoelectric. The present writers carried out similar experiments with aerosol, and found that the electrooptical properties of the mist can be perfectly similar to the properties of hydrophobe colloids. They state that the establishment of the dipolarity of mist particles can possess significance for the explanation of the mechanism governing the aggregation of noncharged particles in mists.

Title : ~~Temperature dependence of relaxation time of luminescence of barium and potassium platinocyanides and fluorite activated by europium~~

Periodical : Zhur. eksp. i teor. fiz., 29, September 1955, 386-387

Abstract : By means of the method of the ultra-taurometer (N. A. Tolstoy, DAN SSSR, 102, 935, 1955) the present writers succeeded for the first time in investigating the kinetics governing the photoluminescence of several substances for which the time of extinction of luminescence lies in the time interval 1/10 to 10 microseconds (the absence of such data on the relaxation of photoluminescence in his time caused S. I. Vavilov to call this interval a blank in luminescence (Izv. AN SSSR, Ser. fiz., 13, 216, 1949). They find that for all three substances ( $K_2[Pt(CN)_4 \cdot 3H_2O$ ,  $CaF_2(Eu^{++})$ , barium platinocyanide) the brightness of luminescence is proportional to the intensity of excitation  $E$  and that the times of extinction and flare-up do not depend upon  $E$ ; thus all three cases are concerned with monomolecular processes representing comparatively slow fluorescence. Title : Instantaneous measurement of light sums of rapidly extinguishing luminescent processes

Periodical : Zhur. eksp. i teor. fiz., 29, Oct 1955, 507-515

Abstract : The authors propose a new objective method for the instantaneous measurement of the light sums  $L_r$  (the area under the curve of phosphorescent flare: razgoraniye fosforetsentsii) and  $L_z$  (the area under the curve of extinguishing: zatukhaniye) for rapidly occurring luminescent processes. They think that the ratio  $L_r/L_z$  can serve as a criterion for the selection of one or another theory of phosphorescence, in as much as the various theories predict different quantities for this ratio. Measurements of this ratio for extinguished ZnS-Cu phosphor indicate the inapplicability of the theory based on the bimolecular mechanism of luminescence and on the monomolecular mechanism of extinguishing. Five references: e.g. N. A. Tolstoy, DAN SSSR, 95, 249, 1954; N. A. Tolstoy and P. P. Feofilov, Izv. AN SSSR, Ser. fiz., 16, 59, 1952.

Title : Formal Analysis of the Theory of the Two-Step Excitation of Phosphorescence and Photoconductivity. I. Stationary Relations.

Orig Pub: Optika i spektroskopiya, 1956, 1, No 2, 216-229

Abstract: A formal analysis is given of the stationary relations of the brightness of glow  $I_\infty$  and the photoconductivity  $\Delta G_\infty$  on the intensity of the exciting light  $E$  in the two-step excitation of phosphorescence and photoconductivity scheme under the assumption that the recombination is subject to the reaction of the first order (pseudomonomolecularity). It is proposed that the primary absorption of the light transfers the electrons to the first step of the scheme (local levels 1, which under definite circumstances can merge in the impurity band). Upon secondary absorption of the light, the electrons are transferred from the first step of excitation to the second

Card : 1/2

USSR / Optics

K

Abs Jour: Referat Zhur-Fizika, 1957, No 4, 10367

to the conduction band (2). Account is taken of the possibility of thermal throwover from the first excitation step into the second ... and also of the repeated adhesions ( $2 \rightarrow 1$ ). It is found that  $n_1$  (the stationary of electrons at levels 1, proportional to the photoconduction over the impurity zone) first increases linearly with increasing  $E$ , and then becomes proportional to  $E^{1/2}$  (the interval in which the "square root" law is valid increases with the increasing probability of the repeated adhesions), and finally, tends to saturation. The quantity  $n_{2\infty}$  (stationary number of electrons in zone 2, proportional to the brightness of glow and to the photoconduction over zone 2) increases with increasing  $E$ , depending on the ratio of the scheme parameters, either (1) first linearly and then superlinearly (up to  $n_{2\infty} \propto E^2$ ) and finally again linearly, or else (2) linearly, sublinearly, and again linearly. The flow yield is estimated for possible ratios of the scheme parameters. The theoretical results are compared with the experimental data on the dependence of  $I_\infty (E)$  and  $\Delta T_\infty (E)$ .
